

Project Report

Karya - Modern Job Portal Platform

Developed by Harsh Kumar Ranjan

24BCS11345

24BCS-KRG-616 B

April 2026

1. Overview

Karya is a modern web-based job portal designed to provide a user-friendly platform where users can explore job opportunities and interact with different sections of a job application system. The main goal of this project is to create a responsive and visually appealing interface that simulates a real-world job portal.

The application is developed using **React.js**, which allows the use of reusable components and efficient state management. Styling is implemented using **Tailwind CSS**, ensuring a responsive design across different screen sizes such as mobile, tablet, and desktop. Navigation within the application is handled by **React Router**, enabling seamless page transitions without reloading the browser.

The project follows a modular structure where the layout is divided into components such as Header, Footer, and individual pages like Home, About, Contact, Login, and Register. This structure improves maintainability and scalability of the application.

Currently, the project focuses on the frontend implementation, providing all necessary user interface elements and interactions. Backend functionalities such as data storage and authentication are planned for future integration.

2. Features of the Project (Functionality)

The Karya Job Portal includes several frontend features that enhance user experience and simulate real-world job portal functionalities.

Core Features

- **Responsive Design:**
The application is fully responsive and adapts to different screen sizes using Tailwind CSS. This ensures usability on mobile phones, tablets, and desktops.
- **Single Page Application (SPA):**
Using React Router, the application behaves as a single-page application where navigation between pages does not require a full page reload.
- **Component-Based Architecture:**
The UI is divided into reusable components such as Header, Footer, and Layout, improving code organization and reusability.
- **Navigation System:**
A fixed navigation bar allows users to move between Home, About, Contact, Login, and Register pages easily.

User Interface Features

- **Home Page:**
Displays a clean interface with a job search bar, job categories, and featured companies. This acts as the landing page for users.
- **Search Bar (Frontend):**
Users can type job-related keywords in the search input field. This feature is designed to later connect with backend search functionality.
- **Categories Section:**
Shows different job categories such as Engineering, Marketing, Sales, etc., providing users with quick navigation options.
- **Featured Companies Section:**
Displays companies actively hiring, along with brief descriptions and ratings.

Authentication UI

- **Login Page:**
A form that allows users to enter email and password. The data is currently handled using React state.
- **Register Page:**
A registration form that collects user details such as name, email, and password.
- **Form Handling:**
Both login and registration forms use controlled components with React state (useState) for managing user input.

Contact Page

- A simple contact form where users can enter their name, email, and message.
- Designed to simulate communication between users and the platform.

3. Flow of the Project

The project flow is based on how users interact with different components and how routing is handled within the application.

Application Flow (Technical)

1. The application starts from the **App.jsx** file.
2. React Router initializes and defines all routes.
3. The **Layout component** is loaded, which includes:
 - Header (Navigation bar)
 - Footer
 - Outlet (for rendering pages)
4. Based on the URL, different components are rendered:
 - / → Home
 - /about → About
 - /contact → Contact
 - /login → Login
 - /register → Register

This structure ensures that Header and Footer remain constant while the content changes dynamically.

User Flow

1. **Landing on Home Page:**

The user opens the application and lands on the Home page, where they can see job categories and featured companies.
2. **Navigation:**

Using the navigation bar, the user can move to different pages such as About, Contact, Login, or Register.

3. **Searching Jobs (UI Level):**

The user enters a keyword in the search bar. Currently, this is a frontend interaction and will later be connected to backend APIs.

4. **Authentication Flow:**

- If the user clicks on Register, they fill out the registration form.
- If the user already has an account, they can navigate to Login.

5. **Form Submission:**

When forms are submitted, the data is handled using React state and logged to the console (simulating backend interaction).

6. **Consistent Layout Experience:**

Throughout the application, the Header and Footer remain visible, providing a consistent user interface.

Future Flow (Planned Backend Integration)

Although not implemented yet, the future backend flow will include:

- Storing user data in a database
- Authenticating users using login credentials
- Fetching jobs dynamically from the server
- Enabling job applications and tracking
